Abstract

Background

Hair loss is becoming a growing problem among students in Bangladesh. While often overlooked as an unimportant concern, it bears severe emotional and psychological effects. Stress, poor diet, academic pressure, and environmental variables are frequently identified as the primary culprits.

Objective

This study looks at the rate and root cause of hair loss among Bangladeshi students, therefore affecting their mental health, social relationships, and academic performance.

Methodology

Data were collected from 100+ students across multiple universities in Bangladesh through an online survey. The survey addressed a variety of subjects, including the seriousness of hair loss, the causes that were felt, academic stress, self-esteem, and social behavior. The responses were analyzed to determine whether there were any correlations between hair loss and academic or psychological effects.

Findings

Over 75% of respondents reported suffering some sort of hair loss. The majority mentioned stress, environmental factors, and academic pressure as potential explanations. Approximately 60% indicated experiencing daily or frequent hair loss. More than 40% mentioned they felt concerned or stressed about their hair regularly. Approximately 35% confessed their confidence in class presentations or social interactions was negatively affected. A smaller but significant group reported skipping social gatherings or facing bullying. Academically, while most indicated the impact was “manageable”, some noticed less focus or motivation.

Conclusion

Hair loss among students is not only a medical issue, but it also links with emotional well-being and academic life. The discrimination around appearance-related concerns can cause stress, particularly in a competitive academic atmosphere. Institutions should explore giving mental health resources and awareness programs to support affected students.
